Bus Ticket Management System

In a Bus Ticket Management System, buses are identified by details such as a Bus number, seating capacity, type (like AC or non-AC), and the driver's name. Each bus is assigned to a specific route, which includes information like route NO, starting point, destination and total distance. Passengers are identified by their Passenger ID, along with personal details such as their name, contact number and e-mail. These passengers can book tickets for different bus routes. Each ticket is associated with a particular passenger and contains important details such as a ticket number, the travel date, the seat number assigned, and the status of the ticket (whether it's booked, confirmed, or canceled). The system ensures that each bus operates on a specific route, while passengers can book multiple tickets for different journeys. Multiple passengers can book seats on the same bus, and the system organizes all the information, ensuring smooth travel arrangements.

Table 2: Bus Table

Bus_No	Seating_Capacity	Type	Driver_Name
001	50	AC	John Doe
002	40	Non-AC	Jane Smith
003	55	AC	Mike Green

Table 3: Route Table

Route_No	Start_Point	Destination	Total_Distance
101	City A	City B	200 km
102	City C	City D	150 km
103	City E	City F	300 km

Table 4: Passenger Table

Passenger_ID	Passenger_Name	Contact_No
P001	Alice Green	1234567890
P002	Bob Brown	0987654321
P003	Carol White	1122334455
P004	David Black	6677889900
P005	Eve Brown	2233445566

After reviewing the 2NF structure, we see that:

1. All tables are in 2nd Normal Form (2NF).
2. None of the non-key attributes depend on other non-key attributes (there are no transitive dependencies).

Therefore, the current structure is already in the 3rd Normal Form (3NF).
